INTRODUCTION

1 Introduction

1.1 Purpose

The purpose of this document is to describe the steps required to integrate the Intel® Firmware Support Package (FSP) into a boot loader solution. It supports CoffeeLake platforms with CoffeeLake processor and CoffeeLake Platform Controller Hub (PCH).

1.2 Intended Audience

This document is targeted at all platform and system developers who need to consume FSP binaries in their boot loader solutions. This includes, but is not limited to: system BIOS developers, boot loader developers, system integrators, as well as end users.

FSP OVERVIEW

FSP Overview

2.1 Technical Overview

The *Intel® Firmware Support Package (FSP)* provides chipset and processor initialization in a format that can easily be incorporated into many existing boot loaders.

The FSP will perform the necessary initialization steps as documented in the BWG including initialization of the CPU, memory controller, chipset and certain bus interfaces, if necessary.

FSP is not a stand-alone boot loader; therefore it needs to be integrated into a host boot loader to carry out other boot loader functions, such as: initializing non-Intel components, conducting bus enumeration, and discovering devices in the system and all industry standard initialization.

The FSP binary can be integrated easily into many different boot loaders, such as Coreboot, EDKII etc. and also into the embedded OS directly.

Below are some required steps for the integration:

- **Customizing** The static FSP configuration parameters are part of the FSP binary and can be customized by external tools that will be provided by Intel.
- **Rebasing** The FSP is not Position Independent Code (PIC) and the whole FSP has to be rebased if it is placed at a location which is different from the preferred address during build process.
- **Placing** Once the FSP binary is ready for integration, the boot loader build process needs to be modified to place this FSP binary at the specific rebasing location identified above.
- **Interfacing** The boot loader needs to add code to setup the operating environment for the FSP, call the FSP with correct parameters and parse the FSP output to retrieve the necessary information returned by the FSP.

2.2 FSP Distribution Package

- The FSP distribution package contains the following:
 - FSP Binary
 - FSP Integration Guide
 - BSF Configuration File
 - Data Structure Header File
- The FSP configuration utility called BCT is available as a separate package. It can be downloaded from link mentioned in Section 1.3.

2.2.1 Package Layout

- **Docs (Auto generated)**
 - CoffeeLake_FSP_Integration_Guide.pdf
 - CoffeeLake_FSP_Integration_Guide.chm
 - **Include**
 - [FspUpd.h](#), [FspmUpd.h](#) and [FspUpd.h](#) (FSP UPD structure and related definitions)
 - [GpioSampleDef.h](#) (Sample enum definitions for Gpio table)
 - CoffeeLakeFspBinPkg.dec (EDKII declaration file for package)
 - Fsp.bsf (BSF file for configuring the data using BCT tool)

FSP INTEGRATION

3 FSP Integration

3.1 Assumptions Used in this Document

The FSP for the CoffeeLake platform is built with a preferred base address given by [PcdFspAreaBaseAddress](#) and so the reference code provided in the document assumes that the FSP is placed at this base address during the final boot loader build. Users may rebase the FSP binary at a different location with Intel's Binary Configuration Tool (BCT) before integrating to the boot loader.

For other assumptions and conventions, please refer section 8 in the FSP External Architecture Specification version 2.0.

3.2 Boot Flow

Please refer Chapter 7 in the FSP External Architecture Specification version 2.0 for Boot flow chart.

3.3 FSP INFO Header

The FSP has an Information Header that provides critical information that is required by the bootloader to successfully interface with the FSP. The structure of the FSP Information Header is documented in the FSP External Architecture Specification version 2.0 with a HeaderRevision of 3.

3.4 FSP Image ID and Revision

FSP information header contains an Image ID field and an Image Revision field that provide the identification and revision information of the FSP binary. It is important to verify these fields while integrating the FSP as AP \leftrightarrow I parameters could change over different FSP IDs and revisions. All the FSP FV segments(FSP-T, FSP-M and FSP-S) must have same FSP Image ID and revision number, using FV segments with different revision numbers in a single FSP image is not valid. The FSP API parameters documented in this integration guide are applicable for the Image ID and Revision specified as below.

The FSP ImageId string in the FSP information header is given by [PcdFspImageIdString](#) and the ImageRevision field is given by [SiliconInitVersionMajor|Minor|FspVersionRevision|FspVersionBuild](#) (Ex:0x07020110).

3.5 FSP Global Data

FSP uses some amount of TempRam area to store FSP global data which contains some critical data like pointers to FSP information headers and UPD configuration regions, FSP/Bootloader stack pointers required for stack switching

etc. HPET Timer register(2) [PcdGlobalDataPointerAddress](#) is reserved to store address of this global data, and hence boot loader should not use this register for any other purpose. If TempRAM initialization is done by boot loader, then HPET has to be initialized to the base so that access to the register will work fine.

3.6 FSP APIs

This release of the CoffeeLake FSP supports the all APIs required by the FSP External Architecture Specification version 2.0. The FSP information header contains the address offset for these APIs. Register usage is described in the FSP External Architecture Specification version 2.0. Any usage not described by the specification is described in the individual sections below.

The below sections will highlight any changes that are specific to this FSP release.

3.6.1 TempRamInit API

Please refer Chapter 8.5 in the FSP External Architecture Specification version 2.0 for complete details including the prototype, parameters and return value details for this API.

TempRamInit does basic early initialization primarily setting up temporary RAM using cache. It returns ECX pointing to beginning of temporary memory and EDX pointing to end of temporary memory + 1. The total temporary ram currently available is given by [PcdTemporaryRamSize](#) starting from the base address of [PcdTemporaryRamBase](#). Out of total temporary memory available, last [PcdFspReservedBufferSize](#) bytes of space reserved by FSP for TempRamInit if temporary RAM initialization is done by FSP and remaining space from **TemporaryRamBase**(ECX) to **TemporaryRamBase+TemporaryRamSize-FspReservedBufferSize** (EDX) is available for both bootloader and FSP binary.

TempRamInit** also sets up the code caching of the region passed CodeCacheBase and CodeCacheLength, which are input parameters to TempRamInitApi. if 0 is passed in for CodeCacheBase, the base used will be 4 GB - 1 - length to be code cached instead of starting from CodeCacheBase.

Note

: when programming MTRR CodeCacheLength will be reduced, if SKU LLC size is smaller than the requested.

It is a requirement for Firmware to have Firmware Interface Table (FIT), which contains pointers to each microcode update. The microcode update is loaded for all logical processors before reset vector. If more than microcode update for the CPU is present, the microcode update with the latest revision is loaded.

FSPT_UPD.MicrocodeRegionBase** and **FSPT_UPD.MicrocodeRegionLength** are input parameters to TempRamInit API. If these values are 0, FSP will not attempt to update microcode. If a region is passed, then if a newer microcode update revision is in the region, it will be loaded by the FSP.

MTRRs are programmed to the default values to have the following memory map:

Memory range	Cache Attribute
0xFE000000 - 0x00040000	Write back
CodeCacheBase - CodeCacheLength	Write protect

3.6.2 FspMemoryInit API

Please refer to Chapter 8.6 in the FSP external Architecture Specification version 2.0 for the prototype, parameters and return value details for this API.

The **FspmUpdPtr** is pointer to [FSPM_UPD](#) structure which is described in header file [FspmUpd.h](#).

Boot Loader must pass valid CAR region for FSP stack use through **FSPM_UPD.FspmArchUpd.StackBase** and **FSPM_UPD.FspmArchUpd.StackSize** UPDs.

The minimum FSP stack size required for this revision of FSP is 160KB, stack base is 0xFE017F00 by default.

The base address of HECI device (Bus 0, Device 22, Function 0) is required to be initialized prior to perform FspMemoryInit flow. The default address is programmed to 0xFED1A000.

Calculate memory map determining memory regions TSEG, IED, GTT, BDSM, ME stolen, Uncore PMRR, IOT, MOT, DPR, REMAP, TOLUD, TOUUD. Programming will be done at a different time.

3.6.3 TempRamExit API

Please refer to Chapter 8.7 in the FSP external Architecture Specification version 2.0 for the prototype, parameters and return value details for this API.

If Boot Loader initializes the Temporary RAM (CAR) and skip calling **TempRamInit API**, it is expected that boot-loader must skip calling this API and bootloader will tear down the temporary memory area setup in the cache and bring the cache to normal mode of operation.

This revision of FSP doesn't have any fields/structure to pass as parameter for this API. Pass Null for *TempRamExitParamPtr*.

At the end of *TempRamExit* the original code and data caching are disabled. FSP will reconfigure all MTRRs as described in the table below for performance optimization.

Memory range	Cache Attribute
0x00000000 - 0x0009FFFF	Write back
0x000C0000 - Top of Low Memory	Write back
0xFF000000 - 0xFFFFFFFF (Flash region)	Write protect

Todo program 0x1000000000 - Top of High Memory | Write back

If the boot loader wish to reconfigure the MTRRs differently, it can be overridden immediately after this API call.

3.6.4 FspSiliconInit API

Please refer to Chapter 8.8 in the FSP external Architecture Specification version 2.0 for the prototype, parameters and return value details for this API.

The *FspUpdPtr* is pointer to **FSPS_UPD** structure which is described in header file [FspUpd.h](#).

It is expected that boot loader will program MTRRs for SBSP as needed after **TempRamExit** but before entering **FspSiliconInit**. If MTRRs are not programmed properly, the boot performance might be impacted.

The region of 0x5_8000 - 0x5_8FFF is used by FspSiliconInit for starting APs. If this data is important to bootloader, then bootloader needs to preserve it before calling FspSiliconInit.

It is a requirement for bootloader to have Firmware Interface Table (FIT), which contains pointers to each microcode. The microcode is loaded for all cores before reset vector. If more than one microcode update for the CPU is present, the latest revision is loaded.

MicrocodeRegionBase and MicrocodeRegionLength are both input parameters to TempRamInit and UPD for SiliconInit API. UPD has priority and will be searched for a later revision than TempRamInit. If MicrocodeRegionBase and MicrocodeRegionLength values are 0, FSP will not attempt to update the microcode. If a microcode region is passed, and if a later revision of microcode is present in this region, FSP will load it.

FSP initializes PCH audio including selecting HD Audio verb table and initializes Codec.

PCH required initialization is done for the following HECI, USB, HSIO, Integrated Sensor Hub, Camera, PCI Express, Vt-d.

FSP initializes CPU features: XD, VMX, AES, IED, HDC, x(2)Apic, Intel® Processor Trace, Three strike counter, Machine check, Cache pre-fetchers, Core PMRR, Power management.

Initializes HECI, DMI, Internal Graphics. Publish EFI_PEI_GRAPHICS_INFO_HOB during normal boot but this HOB will not be published during S3 resume as FSP will not launch the PEI Graphics PEIM during S3 resume.

Programs SA Bars: MchBar, DmiBar, EpBar, GdxcBar, EDRAM (if supported). Please refer to section 2.8 (MemoryMap) for the corresponding Bar values. GttMmadr (0xDF000000) and GmAdr(0xC0000000) are temporarily programmed and cleared after use in FSP.

3.6.5 NotifyPhase API

Please refer Chapter 8.9 in the FSP External Architecture Specification version 2.0 for the prototype, parameters and return value details for this API.

3.6.5.1 PostPciEnumeration Notification

This phase *EnumInitPhaseAfterPciEnumeration* is to be called after PCI enumeration but before execution of third party code such as option ROMs. Currently, nothing is done in this phase, but in the future updates, programming may be done in this phase.

3.6.5.2 ReadyToBoot Notification

This phase *EnumInitPhaseReadyToBoot* is to be called before giving control to boot. It includes some final initialization steps recommended by the BWG, including power management settings, Send ME Message EOP (End of Post).

3.6.5.3 EndOfFirmware Notification

This phase *EnumInitEndOfFirmware* is to be called before the firmware/preboot environment transfers management of all system resources to the OS or next level execution environment. It includes final locking of chipset registers

3.7 Memory Map

Below diagram represents the memory map allocated by FSP including the FSP specific regions.

FSP PORTING RECOMMENDATION

4 FSP Porting Recommendation

Here listed some notes or recommendation when porting with FSP.

4.1 Locking PAM register

FSP 2.0 introduced EndOfFirmware Notify phase callback which is a recommended place for locking PAM registers so FSP by default implemented this way. If it is still too early to lock PAM registers then the PAM locking code inside FSP can be disabled by UPD -> [FSP_S_TEST_CONFIG](#) -> SkipPamLock or SA policy -> [_SI_PREMEM_POLICY_STRUCT](#) -> [SA_MISC_PEL_CONFIG](#) -> SkipPamLock, and platform or wrapper code should do the PAM locking right before booting OS (so do it outside FSP instead) by programming one PCI config space register as below.

This PAM locking step has to been applied in all boot paths including S3 resume. To lock PAM register:

```
MmioOr32 (B0: D0: F0: Register 0x80, BIT0)
```

4.2 Locking SMRAM register

Since SMRAM locking is recommended to be locked before any 3rd party OpROM execution and highly depending on platform code implementation, the FSP code by default will not lock it. The platform or FSP Wrapper code should lock SMRAM by below programming step before any 3rd party OpRom execution (and should be locked in S3 resume right before OS waking vector).

```
PciOr8 (B0: D0: F0: Register 0x88, BIT4); Note: it must be programmed by CF8/CFC Standard PCI access mechanism. (MMIO access will not work)
```

4.3 Locking SMI register

Global SMI bit is recommended to be locked before any 3rd party OpROM execution and highly depending on platform code implementation after SMM configuration. FSP by default will not lock it. Boot loader is responsible for locking below registers after SMM configuration. Set AcpiBase + 0x30[0] to 1b to enable global SMI. Set PMC PCI offset A0h[4] = 1b to lock SMI.

4.4 Verify below settings are correct for your platforms

PMC PciCfgSpace is not PCI compliant. FSP will hide the PMC controller to avoid external software or OS from corrupting the BAR addresses. FSP will program the PMC controller IO and MMIO BAR's with below addresses. Please use this addresses in the wrapper code instead of reading from PMC controller.

Register	Values
ABASE	0x1800
PWRMBASE	0xFE000000
PCIEXBAR_BASE_ADDRESS	0xE0000000

Note

:

- Boot Loader can use different value for PCIEXBAR_BASE_ADDRESS either by modifying the UPD (under FSP-T) or by overriding the PCIEXBAR (B0:D0:F0:R60h) before calling FspMemoryInit Api.
- Boot Loader should avoid using conflicting address when reprogramming PCIEXBAR_BASE_ADDRESS than the recommended one.

4.5 FSP_STATUS_RESET_REQUIRED

As per FSP External Architecture Specification version 2.0, Any reset required in the FSP flow will be reported as return status FSP_STATUS_RESET_REQUIREDx by the API. It is the bootloader responsibility to reset the system according to the reset type requested.

Below table specifies the return status returned by FSP API and the requested reset type.

FSP_STATUS_RESET_REQUIRED Code	Reset Type requested
0x40000001	Cold Reset
0x40000002	Warm Reset
0x40000003	Global Reset - Puts the system to Global reset through Heci or Full Reset through PCH
0x40000004	Reserved
0x40000005	Reserved
0x40000006	Reserved
0x40000007	Reserved
0x40000008	Reserved

FSP OUTPUT

6 FSP Output

The FSP builds a series of data structures called the Hand-Off-Blocks (HOBs) as it progresses through initializing the silicon.

Please refer to the Platform Initialization (PI) Specification - Volume 3: Shared Architectural Elements specification for PI Architectural HOBs. Please refer Chapter 9 in the FSP External Architecture Specification version 2.0 for details about FSP Architectural HOBs.

Below section describe the HOBs not covered in the above two specifications.

6.1 SMRAM Resource Descriptor HOB

The FSP will report the system SMRAM T-SEG range through a generic resource HOB if T-SEG is enabled. The owner field of the HOB identifies the owner as T-SEG.

```
#define FSP_HOB_RESOURCE_OWNER_TSEG_GUID \
{ 0xd038747c, 0xd00c, 0x4980, { 0xb3, 0x19, 0x49, 0x01, 0x99, 0xa4, 0x7d, 0x55 } }
```

6.2 SMBIOS INFO HOB

The FSP will report the SMBIOS through a HOB with below GUID. This information can be consumed by the bootloader to produce the SMBIOS tables. These structures are included as part of [MemInfoHob.h](#) , [SmbiosCacheInfoHob.h](#), [SmbiosProcessorInfoHob.h](#) & [FirmwareVersionInfoHob.h](#)

FSP POSTCODE

7 FSP PostCode

The FSP outputs 16 bit postcode to indicate which API and in which module the execution is happening.

Bit Range	Description
Bit15 - Bit12 (X)	used to indicate the phase/api under which the code is executing
Bit11 - Bit8 (Y)	used to indicate the module
Bit7 (ZZ bit 7)	reserved for error
Bit6 - Bit0 (ZZ)	individual codes

Enumerator

GpioHostOwnDefault Leave ownership value unmodified.

GpioHostOwnAcpi Set HOST ownership to ACPI. Use this setting if pad is not going to be used by GPIO OS driver. If GPIO is configured to generate SCI/SMI/NMI then this setting must be used for interrupts to work

GpioHostOwnGpio Set HOST ownership to GPIO Driver mode. Use this setting only if GPIO pad should be controlled by GPIO OS Driver. GPIO OS Driver will be able to control the pad if appropriate entry in ACPI exists (refer to ACPI specification for GpioIo and GpioInt descriptors)

Definition at line 128 of file GpioConfig.h.

13.8.2.5 enum GPIO_INT_CONFIG

GPIO interrupt configuration This setting is applicable only if pad is in GPIO mode and has input enabled.

GPIO_INT_CONFIG allows to choose which interrupt is generated (IOxAPIC/SCI/SMI/NMI) and how it is triggered (edge or level). Refer to PADCFG_DW0 register description in EDS for details on this settings. Field from GpioIntNmi to GpioIntApic can be OR'ed with GpioIntLevel to GpioIntBothEdge to describe an interrupt e.g. GpioIntApic | GpioIntLevel If GPIO is set to cause an SCI then also GPI_GPE_EN is enabled for this pad. If GPIO is set to cause an NMI then also GPI_NMI_EN is enabled for this pad. Not all GPIO are capable of generating an SMI or NMI interrupt. When routing GPIO to cause an IOxAPIC interrupt care must be taken, as this interrupt cannot be shared and its IRQn number is not configurable. Refer to EDS for GPIO pads IRQ numbers (PADCFG_DW1.IntSel) If GPIO is under GPIO OS driver control and appropriate ACPI GpioInt descriptor exist then use only trigger type setting (from GpioIntLevel to GpioIntBothEdge). This type of GPIO Driver interrupt doesn't have any additional routing setting required to be set by BIOS. Interrupt is handled by GPIO OS Driver.

Enumerator

GpioIntDefault Leave value of interrupt routing unmodified.

GpioIntDis Disable IOxAPIC/SCI/SMI/NMI interrupt generation.

GpioIntNmi Enable NMI interrupt only.

GpioIntSmi Enable SMI interrupt only.

GpioIntSci Enable SCI interrupt only.

GpioIntApic Enable IOxAPIC interrupt only.

GpioIntLevel Set interrupt as level triggered.

GpioIntEdge Set interrupt as edge triggered (type of edge depends on input inversion)

GpioIntLvlEdgDis Disable interrupt trigger.

GpioIntBothEdge Set interrupt as both edge triggered.

Definition at line 189 of file GpioConfig.h.

13.8.2.6 enum GPIO_LOCK_CONFIG

GPIO LockConfiguration Set GPIO configuration lock and output state lock.

GpioPadConfigUnlock/Lock and GpioOutputStateUnlock can be OR'ed. By default GPIO pads will be locked unless GPIO lib is explicitly informed that certain pad is to be left unlocked. Lock settings reset is in Powergood domain. Care must be taken when using this setting as fields it locks may be reset by a different signal and can be controlled by what is in GPIO_RESET_CONFIG (PADCFG_DW0.PadRstCfg). GPIO library provides functions which allow to unlock a GPIO pad. If possible each GPIO lib function will try to unlock an already locked pad upon request for reconfiguration

Enumerator

GpioLockDefault Perform default action.

- if pad is an GPO, lock configuration but leave output unlocked
- if pad is an GPI, lock everything
- if pad is in native, lock everything

GpioPadConfigUnlock Leave Pad configuration unlocked.

GpioPadConfigLock Lock Pad configuration.

GpioOutputStateUnlock Leave Pad output control unlocked.

GpioPadUnlock Leave both Pad configuration and output control unlocked.

GpioPadLock Lock both Pad configuration and output control.

Definition at line 297 of file GpioConfig.h.

13.8.2.7 enum GPIO_OTHER_CONFIG

Other GPIO Configuration GPIO_OTHER_CONFIG is used for less often settings and for future extensions Supported settings:

- RX raw override to '1' - allows to override input value to '1' This setting is applicable only if in input mode (both in GPIO and native usage). The override takes place at the internal pad state directly from buffer and before the RXINV.

Enumerator

GpioRxRaw1Default Use default input override value.

GpioRxRaw1Dis Don't override input.

GpioRxRaw1En Override input to '1'.

Definition at line 323 of file GpioConfig.h.

13.8.2.8 enum GPIO_OUTPUT_STATE

GPIO Output State This field is relevant only if output is enabled.

Enumerator

GpioOutDefault Leave output value unmodified.

GpioOutLow Set output to low.

GpioOutHigh Set output to high.

Definition at line 163 of file GpioConfig.h.

13.8.2.9 enum GPIO_PAD_MODE

GPIO Pad Mode Refer to GPIO documentation on native functions available for certain pad.

If GPIO is set to one of NativeX modes then following settings are not applicable and can be skipped:

- Interrupt related settings
- Host Software Ownership
- Output/Input enabling/disabling
- Output lock

Definition at line 113 of file GpioConfig.h.

13.8.2.10 enum GPIO_RESET_CONFIG

GPIO Power Configuration GPIO_RESET_CONFIG allows to set GPIO Reset type (PADCFG_DW0.PadRstCfg) which will be used to reset certain GPIO settings.

Refer to EDS for settings that are controllable by PadRstCfg.

Enumerator

GpioResetDefault Leave value of pad reset unmodified.

GpioResumeReset Resume Reset (RSMRST) GPP: PadRstCfg = 00b = "Powergood" GPD: PadRstCfg = 11b = "Resume Reset" Pad setting will reset on:

- DeepSx transition
- G3 Pad settings will not reset on:
- S3/S4/S5 transition
- Warm/Cold/Global reset

GpioHostDeepReset Host Deep Reset PadRstCfg = 01b = "Deep GPIO Reset" Pad settings will reset on:

- Warm/Cold/Global reset
- DeepSx transition
- G3 Pad settings will not reset on:
- S3/S4/S5 transition

GpioPlatformReset Platform Reset (PLTRST) PadRstCfg = 10b = "GPIO Reset" Pad settings will reset on:

- S3/S4/S5 transition
- Warm/Cold/Global reset
- DeepSx transition
- G3

GpioDswReset Deep Sleep Well Reset (DSW_PWROK) GPP: not applicable GPD: PadRstCfg = 00b = "↔ Powergood" Pad settings will reset on:

- G3 Pad settings will not reset on:
- S3/S4/S5 transition
- Warm/Cold/Global reset
- DeepSx transition
